Motivation: Cancer progression is a complex phenomenon that spans multiple scales from molecular to cellular and intercellular. Simulations can be used to perturb the underlying mechanisms of those systems and to generate hypotheses on novel therapies. We present a new version of PhysiBoSS, a multiscale modelling framework designed to cover multiple temporal and spatial scales, that improves its integration with PhysiCell, decoupling the cell agent simulations with the internal Boolean model in an easy-to-maintain computational framework.

Results: PhysiBoSS 2.0 is a redesign and reimplementation of PhysiBoSS, conceived as an add-on that expands the PhysiCell agent-based functionalities with intracellular cell signalling using MaBoSS having a decoupled, maintainable and model-agnostic design. PhysiBoSS 2.0 successfully reproduces simulations reported in the former PhysiBoSS and expands its functionalities such as using user-defined models and cells' specifications, having mechanistic submodels of substrate internalisation with ODEs and enabling the study of drug synergies.

Availability and implementation: PhysiBoSS 2.0 is open-source and publicly available on GitHub (<https://github.com/PhysiBoSS/PhysiBoSS>) under the BSD 3-clause license. Additionally, a nanoHUB tool has been set up to ease the use of PhysiBoSS 2.0 (<https://nanohub.org/tools/pba4tnf/>).

Introduction

PhysiBoSS (Letort *et al.*, 2019) is a standalone multiscale simulation software that was implemented by coupling an early version of PhysiCell (Ghaffarizadeh *et al.*, 2018), a multiscale multicellular agent-based software that can help understand the role of the interactions between cells and their environment, and MaBoSS (Stoll *et al.*, 2012), a continuous-time Markovian simulator for Boolean models that describe cell's intracellular signalling. Nevertheless, PhysiBoSS presented some design problems: it can not be easily upgraded to use the current versions of any of those two pieces of software, hindering its long-term maintenance, and lacks a clear interface between these two tools, resulting in a software hard to modify and to extend without changing core functionalities.

Herein, we present PhysiBoSS 2.0, a redesign and reimplementations of PhysiBoSS. PhysiBoSS 2.0 add-on is implemented so that both PhysiCell and MaBoSS are decoupled and therefore can be upgraded independently. Furthermore, the code was designed and implemented following the best practices guidelines for bioinformatics software development, ensuring its long-term maintenance and prolonging its lifespan (Mangul *et al.*, 2019).

Additionally, PhysiBoSS 2.0 includes new functionalities like allowing the use of highly customisable settings such as user-defined Boolean models and cell types in the configuration XML, by easing the building of user-defined examples with different Boolean models in different cell types and by enabling the study of drug effects and synergies in multiscale simulations. PhysiBoSS 2.0 is a step towards the development of a PhysiCell add-ons ecosystem of different types of models (Macklin *et al.*, 2018) that allows for the scaling-up of simulations in exascale high-performance computing clusters (Montagud, Ponce-de-Leon, *et al.*, 2021; Saxena *et al.*, 2021).

Method and implementation

PhysiBoSS 2.0 was designed as an add-on interface that integrates PhysiCell and MaBoSS frameworks, reducing their dependencies and enabling new functionalities. This design simplifies the tool's maintenance and allows for their independent upgrade. The software is written in C++ and OpenMP is available to parallelise the execution. The implementation is described in further detail in the Supplementary Information together with a template project for new users. PhysiBoSS 2.0 code is open source and is distributed under BSD 3-clause license and is available at <https://github.com/PhysiBoSS/PhysiBoSS>. We also provide a nanoHUB GUI-based tool implementing an example model to ease its use at <https://nanohub.org/tools/pba4tnf/>.

Results

The new design of PhysiBoSS 2.0 allows for new functionalities

PhysiBoSS embedded MaBoSS in PhysiCell and modified and adapted several core classes of the latter, burdening the updatability of these pieces of software. PhysiBoSS 2.0 design solves this maintainability issue by decoupling PhysiCell and MaBoSS with an interfacing add-on between them (Figure 1A, Supplementary Figure S1).

This decoupling is obtained by encapsulating the functionalities used to simulate the Boolean model in a dedicated *MaBoSSNetwork* class that uses the MaBoSS library to store the current Boolean state of the cell and perform the simulations. This class is then used in a specialised implementation of the *Intracellular* class (*MaBoSSIntracellular*), which describes how to import and simulate a MaBoSS intracellular model. This modularisation allows our code to be more easily maintainable. In addition, this add-on connection has been incorporated into the main PhysiCell code for this and other intracellular models (Macklin *et al.*, 2018) (Supplementary Information and Figure S1).

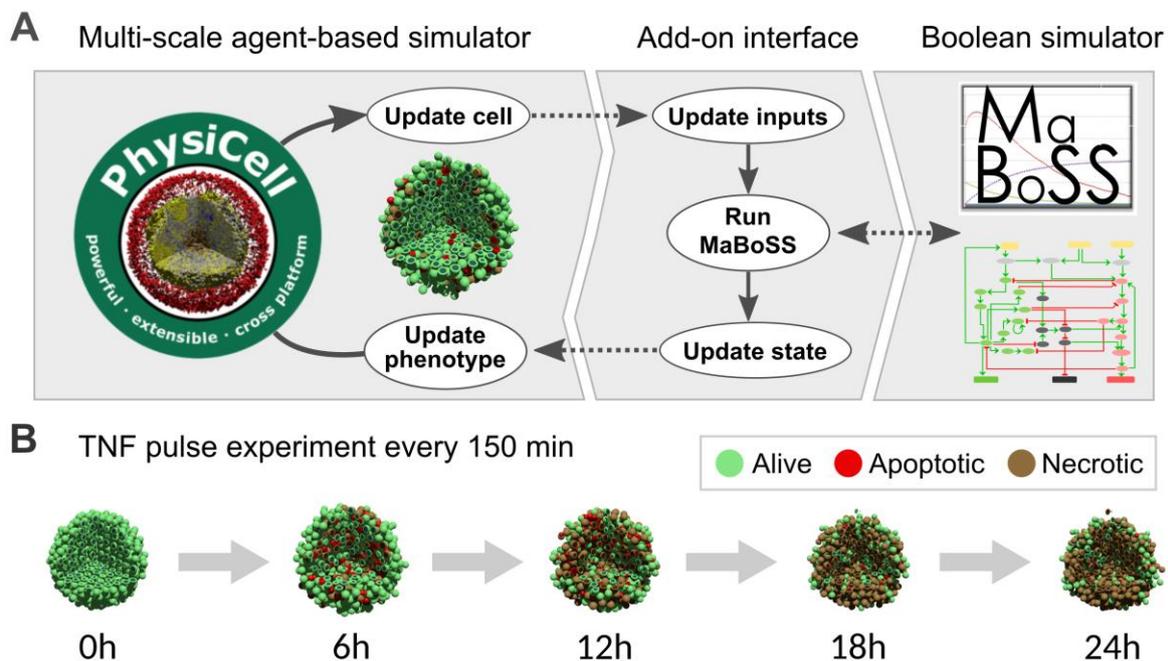

Figure 1. PhysiBoSS 2.0 add-on-based design. A) Scheme of the add-on-based design of PhysiBoSS 2.0 that decouples PhysiCell and MaBoSS, providing Boolean simulation functionality to individual cell agents in a maintainable manner. B) Example of a simulation in PhysiBoSS 2.0 that reproduces the complex simulations presented in Letort *et al.* (2019) work, where a tumour spheroid is supplied with periodic pulses of tumour necrotic factor (TNF) every 150 minutes (Supplementary Information and Figure S7).

This decoupling design facilitates the use of the latest versions of MaBoSS and PhysiCell, allowing PhysiBoSS 2.0 to incorporate new features that enable studies that were not possible with the former PhysiBoSS. For instance, by using PhysiCell 1.9, we can track internalised substrates in cells, use configuration XML files to specify cell types and have cell-cell contact behaviours. Also, by using MaBoSS 2.3.4, we can work with Boolean models with more than 64 nodes, use OpenMP to parallelise the simulation, be able to run under Microsoft Windows OS, run different Boolean models in the same simulation and define these models in the SBML standard (Supplementary Information, Figure S8 and S9).

Additionally, our design allows PhysiBoSS 2.0 to ease the integration of new Boolean models by using custom modules that connect intracellular variables to agent-based ones and configuration XML files with custom data for different cell types and environments that is a beta feature of PhysiCell 1.7.1.

PhysiBoSS 2.0 enables multiscale modelling that uncovers mechanisms of drug treatments and synergies.

The decoupling of the codes allows for users to have unprecedented flexibility in studying more complex multiscale models that bridge different time and space scales. We showcase here two examples: the integration of a transport module for environmental substrates and the integration of pharmacodynamics and Boolean models to study drug combinations.

We incorporated an ODE-based transport module into an already published Boolean model that studies the cells' response to different tumour necrosis factor (TNF) dosage recipes (Calzone *et al.*, 2010). We replicated work reported by Letort, *et al.* (2019) using this model that showed complex dynamics and emergent behaviour: continuous exposures to TNF resulted in cells becoming resistant to the effect of the cytokine, whereas short pulses of a certain frequency caused the reduction of the tumour spheroid (Figure 1B). The TNF transport module focuses on the substrate's receptor dynamics allowing for the explicit modelling of the transport of environmental substrates such as nutrients and drugs inside the agents using ODEs and studying their effects on the Boolean model. This transport module can be user-defined to capture the particularities of different nutrients and drugs and it can be used to find optimal drug regimes (Akasiadis *et al.*, 2021; Ponce-de-Leon *et al.*, 2021).

As the parameters of the new example (based on PhysiCell 1.9) do not have a one-to-one mapping to those of the former PhysiBoSS example (based on PhysiCell 1.0), we used a model exploration method (Ozik *et al.*, 2018) to find parameters that reproduce the dynamics previously reported (Supplementary Information, Figure S1). We have deployed a PhysiBoSS 2.0 instance running this example to facilitate the study of different parameters sets (<https://nanohub.org/tools/pba4tnf/>). In addition, the PhysiBoSS 2.0 results were consistent with the PhysiBoSS publication ones, as evidence of the correctness of our reimplementation (Supplementary Information and Figure S7).

In addition, PhysiBoSS 2.0 enables the performance of drug studies such as synergy predictions in cell populations while considering heterogeneities among the cells and the environment. By using personalised Boolean models (Béal *et al.*, 2019) and GDSC dose-response profiling data (Vis *et al.*, 2016), we can portray the typical characteristics of cell lines and drugs. Then, with PhysiBoSS 2.0, we can perform multiscale simulations and find synergistic drug combinations for a cell line of interest. We hereby provide an example study on the LNCaP prostate cell line (Montagud, Béal, *et al.*, 2021) with six different drugs (Supplementary Information). We identified two combinations of drugs as interesting: *Pictilisib* (targeting PI3K) with *Ipatasertib* (targeting AKT) and *Pictilisib* with *Luminespib* (targeting HSPs) (Table S2). In both of them, we see that the Growth Index (a measure of the relative growth of treated cells vs untreated cells, see Supplementary Information) for LNCaP is much lower when using both drugs than when using individual drugs (Figure 2 and S3). In addition, we studied the Bliss independence of these combinations (Figure 3 and S4) and found complex synergies in both cases (Supplementary Information, Section 3.3).

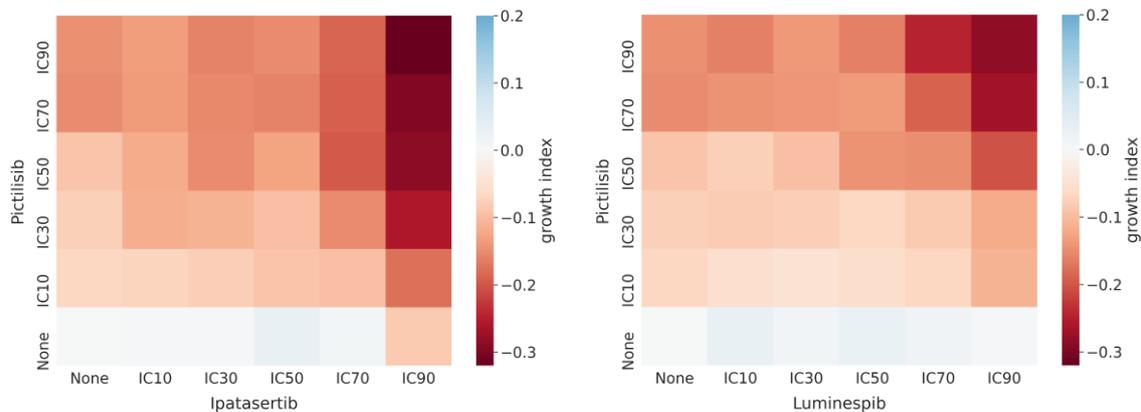

Figure 2: Growth index of a multiscale simulation of LNCaP with *Pictilisib* + *Ipatasertib* (left) and *Pictilisib* + *Luminespib* (right) with respect to the untreated LNCaP. Each simulation was replicated 10 times. For each combination, the growth index was obtained by taking the log₂ of the ratio between the median AUC upon drug administration and the median AUC of the untreated simulations. White colour means no growth behaviour change upon drug administration, blue means the drug increased the growth and red means that the drug diminished the growth of the cells.

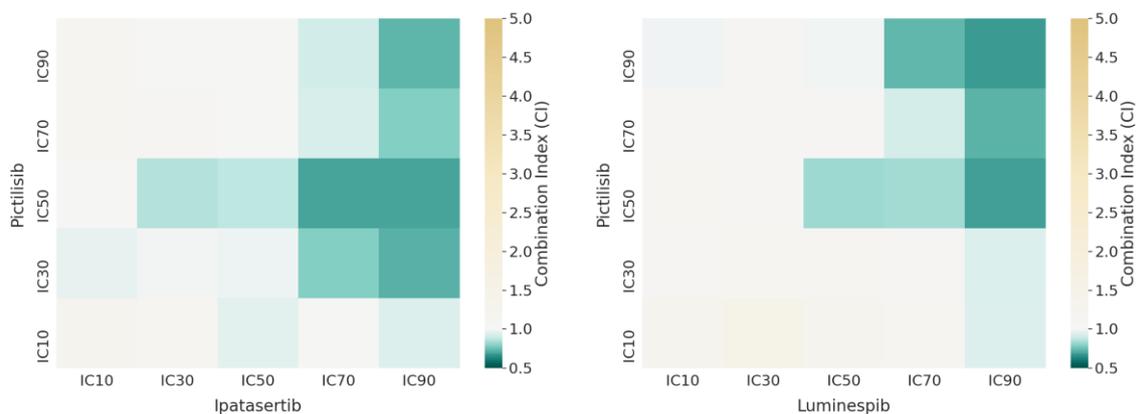

Figure 3: Bliss independence combination Index (CI) of a multiscale simulation of LNCaP with *Pictilisib* + *Ipatasertib* (left) and *Luminespib* + *Pictilisib* (right), White colour indicates an additive effect; Green colour a synergistic effect; Yellow an antagonistic effect.

The complete study of LNCaP and six drugs (Ipatasertib targeting AKT, Luminespib targeting HSPs, Pictilisib targeting PI3K, Afatinib targeting EGFR, Ulixertinib targeting MAPK1, Selumetinib targeting MAP2K1 and MAP2K2) can be found in the Supplementary Information together with the same analysis for the AGS gastric cell line (Flobak *et al.*, 2015) and 7 drugs of interest (Figures S5 and S6).

With these capabilities, PhysiBoSS 2.0 takes an important step towards the study of drug treatments and effective drug synergies, a further step to reach a truly personalised medicine and to help improve treatments for cancer patients. Implicitly, this also showcases the flexibility of PhysiBoSS 2.0 to run with any user-provided Boolean model in MaBoSS or SBML-qual format, as opposed to the former PhysiBoSS.

Conclusions

PhysiBoSS 2.0 is a redesign and reimplement of PhysiBoSS to be a reusable, extensible and updatable add-on for the PhysiCell framework. Our tool follows a modular design that decouples PhysiCell and MaBoSS codes, minimising the dependencies between these tools

and ensuring long-term maintainability and is, therefore, more respectful of the single responsibility principle and the façade pattern software design (Johnson *et al.*, 1995).

We show added functionalities that enable PhysiBoSS 2.0 to study disease mechanisms that cause malfunctions in personalised models while being consistent with the results of the former PhysiBoSS and flexible to handle many models. Altogether, the new design and implementation allow PhysiBoSS 2.0 to be model-agnostic, easily customisable by users and provides a simple framework of custom modules and custom settings to use with any Boolean model of interest in MaBoSS or SBML-qual format.
